Q: C# Allowing an application to display the currently logged in user I'm programming a client app which will need to fetch data from the web and display it to the user. However, before I start doing this I want to make sure that the user is logged in to a specific section of the site. By logging in I mean that when the user opens the program they'll be prompted to enter a username, password and their email. How do I make the application know whether the current user is logged in? A: There are many approaches to this but the most common one is to store the username and password in a file and check whether they are valid against the credentials of the current user when opening the program. Another approach is to make an HTTP request to the URL of the "login" page, check the response headers and take the necessary actions. If you search, you will find several approaches. Here's one example. private void CheckUnauthorizedAccess(HttpContext context) { string UserName = context.User.Identity.Name.Split('\')[1].ToString(); string Password = context.User.Identity.Name.Split('\')[2].ToString(); string RedirectUrl = context.Request.Url.AbsolutePath; if (!context.Session["USERNAME"] &&!Password.Equals(context.User.Identity.Name)) { context.Response.Redirect(RedirectUrl); } else { string UserPass = context.Request.QueryString.ToString(); context.Response.Redirect(context.Request.Url.AbsolutePath); } } Google has signed an agreement with a minor party to run the Chrome browser on a majority of the new Android devices when they ship, according to a report from Reuters. The news agency says that a source close to Google has confirmed that Google and Samsung have settled on an agreement that will obligate Android to ship Chrome when a device reaches consumers. The person Reuters describes as a "highly placed source" told the news agency that the details have yet to be finalized, and "the

Q: Is it standard to declare a type in an environment as a "strided" vector? When discussing containers with the STL, I found that it is commonly (if not always) accepted to say "vector t" or "vector > t". It is also accepted to say "vector >> t" or even "vector>>> t". I've seen this being done in a few different code examples, and when I think about it I accept it as a "standard" technique. But in all of these examples the type was declared as a vanilla vector that always has 3 entries. Is it standard to extend a type to also be able to have more than 3 entries. For example, in reality, would a vector of ints that can hold 10 entries just be t? A: The FAQ says: Is it legal to declare a type like this: vector>>? It's not legal because C++ Standard 5.2/4 is not a vector type: The elements of such an array are references to the elements of the original array that is being replaced. Once all the elements of the original array have been replaced, the original array is destroyed and the elements referenced by the elements of the array that is being replaced are destroyed. Note that the last sentence there is relevant - the elements you're using are a "reference to" the elements from the original array, not "directly a copy" of the elements. Lumbar intervertebral disc narrowing with and without a bone spur at L5-S1: advanced MR imaging study. To evaluate intervertebral disc narrowing with and without a bone spur in asymptomatic patients and to determine whether this finding predicts future clinical symptoms. A total of 168 patients (96 women and 72 men; mean age, 38.8 years; range, 17 to 73 years) with no history of low-back pain or sciatica underwent magnetic resonance (MR) imaging at 1.5 T for diagnosis. The signal intensities and cross-sectional areas of the disc were measured by placing a region of interest in the paravertebral disc space on T2-weighted sagittal MR images. A bone spur was also evaluated in disc space of L5-S1. Intervertebral disc narrowing of L5
