The present invention relates to a catheter tube for medical use such as an infusion catheter, a transfusion catheter, or an angioplasty catheter, and more specifically to a catheter tube having a fine-scaled structure for medical use. A percutaneous indwelling catheter is used for long-term therapy or parenteral administration of special drugs or blood products. As the indwelling time becomes longer, there is a growing concern over the development of an infection by bacteria, fungi or viruses (endotoxin or cytotoxin) in the catheter. As a result, there have been developed devices and methodologies in which the inside of the catheter is sterilized by an antibacterial agent or a filter or a low-protein-reactivity material is used as a medical material. The antibacterial agent in general has the following drawbacks. That is, the material for forming the catheter has a relatively large inner diameter, has a large weight, and is poor in flexibility, so that it is not easy to insert into a blood vessel. As a result, a large amount of the antibacterial agent is used in order to cover the inner wall of the catheter, which disadvantageously causes a heavy burden to the patient in the course of treatment. Since the antibacterial agent can be eluted into the blood, it gives a risk of causing side-effects such as blood coagulation. On the other hand, a filter material is poor in flexibility, in turn having the drawbacks of difficulty in use and in the management of the unused portion. Furthermore, the material is so low in gas-barrier property that the inside of the catheter is not fully sterilized but the bacteria, fungi or viruses will enter the blood through a portion of the material. Further, the material is costly. On the other hand, a medical tube formed of a low-protein-reactivity material such as polyvinylidene fluoride (PVDF) (trade name of PELF, polyvinylidene fluoride) or polyethylene (PE) is known to have a relatively high gas-barrier property. However, the material is heavy and inferior in flexibility, thereby preventing the material from being practically used.

Advanced Ball Light Technology is the light weight and handy way of showing the balls' distribution on the field. The Advanced Ball Light Technology (ABLT), which means light in weight, is a highly sensitive, state-of-the-art, weightless, light-emitting ball that can be used in a variety of different ways on the football field. It is used to indicate the activity of the players on the field. This ball can also be used for training, as it is very light and has a single LED that blinks, depending on the real ball speed on the field. If the LED blinks on the field, it means that the ball is distributed over the field and if it blinks it means that the ball is moving with a slow speed. Me and a friend of mine drive a z4 m23. The problem is, that while we have to go for a certain stretches around 15+ mph, the only traffic we really encounter is much slower, and thats no problem. But, near highways, in particular near where I live, driving is way too slow. And when there are car/traffic jams, then we have to accelerate to speeds of about 40-45 mph, just to get there. Its really annoying. Is it maybe possible to have some kind of turbocharger, so that we can gain some additional power without having to speed up that much? If it's head pressure on the low side, then the (water-cooled) engine might not have enough flow through it to handle it without escalating rpm over normal. Is it air not going into the intake manifold? If the throttle is open, the EGR valve might not be open for some reason. Is it not opening? Is there a vacuum leak anywhere in the intake air system? The gas pedal cable could be disconnected, or could be partially disconnected. Is the accelerator linkage completely free? You could try and remove the gas tank from the car, and perform a visual inspection of everything to make sure it isn't hanging up somewhere.
