issues in pediatric medicine. ADD is defined as a disorder that is characterized by symptoms of inattention and hyperactivity. According to the DSM-III-R classification, ADD is divided into two subtypes: the predominantly inattentive and the predominantly hyperactive. The inattentive subtype is characterized by relatively selective impairment of attention, cognitive performance and motor control. In contrast, the hyperactive-impulsive subtype shows a tendency toward impulsive behavior, without being able to control these actions. Despite recent progress made in the clinical diagnosis of ADD, controversy exists concerning the criteria for the optimal diagnosis of this disorder and its subtypes. Due to the high incidence of psychiatric comorbidities with ADD, there is also a need to elucidate the nature of these co-morbidities and their correlation with ADD subtypes. In this paper, we discuss the history and development of the clinical diagnosis of ADD and its subtypes with special attention to the controversy that exists regarding their criteria and their relationships with the various co-morbidities and temperament traits associated with ADD. return (void
