It seems to me that a one bit pattern, can be matched by a register.

This is because there are only two possibilities, true or false, and no choice between them.

However, if we put the same pattern into two registers, we now have a choice between them. This is because the true values of the first register and the false values of the second register are both valid, and we must perform an operation on them, which would be merging

them into one value. In my opinion, a bit pattern cannot be matched by only one bit of a register because there is a 2-bit pattern that can still be matched. Since, in assembly there is always more than one way to solve a problem, can this be shown? A: It's an incorrect conclusion. Using one of your examples, let's say the first register A has the value 0111_1101,

which is 11011100. The second register B has the value 0111_1110, which is 11001000. If we apply a binary AND operation to register B and the first register A, we get 0111_1111_1011, which is 0000000000000000_1. This is valid, of course. It's the result of ANDing the true value of register B (11 d0c515b9f4
