1. If you open an image, a window titled Image Bin opens with a rotating 3-D-looks-like an actual 3D box. The Image Bin or 3D Preview window allows you to see at a glance the size, resolution, format, and file attributes for the image. You can have five image bins open simultaneously. 2. In the Layers Panel (Window > Layers), you see various layers. You usually have a Background layer that shows your image in white. Under the Background layer is your image (in black), which is called the active layer. Over the active layer, you see a transparent layer called the Clip Mask. Click this to activate the clip mask to enable all actions to be applied to the active layer. When you remove the clipping, any effects that you apply to the active layer will be applied to the original. 3. To edit the active layer, double-click it to open the Layers Panel. You can make changes in the Control Panel. It's the top portion of the Layers Panel. Each item is a tool. The tools you can use in the Control Panel are listed on the left, and each tool has a shortcut key. The default shortcut key is shown at the top of the tool. You can change the shortcut key for any tool you like. 4. When you want to edit the entire image, go to View > Quick Selection Tool (Q). When you click on the Quick Selection Tool icon, you see a black square with a white arrow on the top right side. Click and drag to select the entire image. If you click the top right, it will show you the image window, and if you click the bottom right, it will exit image mode.

Q: Is there a way to tell which panning technique is being used in a video? I'm trying to write code that will allow the user to choose a panning technique to apply to a video. I've come up with two ideas: Get the audio data from the video and extract time (position) data from it. The user can then select one of the techniques to apply to the video. Get the video data from the video and use a combination of video decoding and demuxing to extract time data from the video file. Whichever way I choose to do this I want to make sure that it's possible to access the data in some standard way. Is there a way to do this in a way that lets me get the data out as easily as possible? A: Often it is simply the case that a user will use the default timeline functions. This is why you should not rely upon always knowing what is already available. There's no law that says you always need to do all the setup and testing first. I cannot speak specifically to what language you are using, but if you are working in C++, I'd recommend using ffmpeg for what you are trying to achieve. It will give you access to the input video through frames, and it will give you access to the audio through a format similar to the frames through AVCodec's. You would use this program to process the video and extract the frames. Before you do anything else, you can get the current frame and determine the position, with the help of a seek function like : av_seek_frame Just a thought... Warner Bros. Pictures ended up being the most watched movie last weekend, with a good amount of it being due to the Batman v Superman: Dawn of Justice hype. However, most of the analysts still rated Suicide Squad as the winner of the week, and that isn't even close to being the truth. Well, it isn't, until you read this article. The box office ranking is simple. A movie that grosses the most money during its first week of opening is considered a success. A movie that is the most popular that particular week is considered a success. Even though Hollywood has more than 7,000 movies in their line-up, the movie that makes the most money during the first week is what the studios put the effort in to improve on the most.

Q: How do I determine the date/time of an entry in a tableview? So, I have a tableview that displays statistics of something I've been doing with my phone. I want to add an update button which will refresh the screen based on the time. Now, I'm not using some sort of framework. I created the tableview manually. I created the button in IB, and created the code to call it manually, (the code I had for my original implementation was to constantly call a callback, which did nothing other than try and call itself infinitely). But I want to make it so that it only updates whenever the device is not already refreshing. I need some sort of reference of "now". I've been looking around, but can't seem to find any "now" reference anywhere. Any hints? A: You could useNSUserDefaults. Simply create a NSString from a string representation of a NSDate. So if you are using a NSDateFormatter like Gregorian, use NSDateFormatter.dateFromString:. +++ Title = "Keyvan Ahmadi" Twitter = "keyvan" image = "keyvan-a.jpg" type = "speaker" linktitle = "keyvan-a" +++ - Computers and mobile applications developer and technologist - I'm a maniacal coffee drinker who also enjoys art, football and tennis - I love to speak and listen and share things with the community and the world
